Linux Programmer's Manual

READDIR(3)

```
NAME top
```

```
readdir, readdir r - read a directory
```

SYNOPSIS top

```
#include <dirent.h>
struct dirent *readdir(DIR *dirp);
int readdir_r(DIR *dirp, struct dirent *entry, struct dirent **result);
Feature Test Macro Requirements for glibc (see feature_test_macros(7)):
    readdir_r():
        _POSIX_C_SOURCE >= 1 || _XOPEN_SOURCE || _BSD_SOURCE ||
        _SVID_SOURCE || _POSIX_SOURCE
```

DESCRIPTION top

The **readdir**() function returns a pointer to a *dirent* structure representing the next directory entry in the directory stream pointed to by *dirp*. It returns NULL on reaching the end of the directory stream or if an error occurred.

On Linux, the *dirent* structure is defined as follows:

The only fields in the dirent structure that are mandated by POSIX.1

are: $d_name[]$, of unspecified size, with at most NAME_MAX characters preceding the terminating null byte ('\0'); and (as an XSI extension) d_ino . The other fields are unstandardized, and not present on all systems; see NOTES below for some further details.

The data returned by **readdir**() may be overwritten by subsequent calls to **readdir**() for the same directory stream.

The **readdir_r**() function is a reentrant version of **readdir**(). It reads the next directory entry from the directory stream *dirp*, and returns it in the caller-allocated buffer pointed to by *entry*. (See NOTES for information on allocating this buffer.) A pointer to the returned item is placed in *result; if the end of the directory stream was encountered, then NULL is instead returned in *result.

RETURN VALUE top

On success, **readdir**() returns a pointer to a *dirent* structure. (This structure may be statically allocated; do not attempt to free(3) it.) If the end of the directory stream is reached, NULL is returned and *errno* is not changed. If an error occurs, NULL is returned and *errno* is set appropriately.

The **readdir_r**() function returns 0 on success. On error, it returns a positive error number (listed under ERRORS). If the end of the directory stream is reached, **readdir_r**() returns 0, and returns NULL in *result.

ERRORS top

EBADF Invalid directory stream descriptor dirp.

ATTRIBUTES top

```
Multithreading (see pthreads(7))
```

The **readdir**() function is not thread-safe.

The **readdir_r**() function is thread-safe.

CONFORMING TO top

SVr4, 4.3BSD, POSIX.1-2001.

NOTES top

Only the fields <code>d_name</code> and <code>d_ino</code> are specified in POSIX.1-2001. The remaining fields are available on many, but not all systems. Under glibc, programs can check for the availability of the fields not defined in POSIX.1 by testing whether the macros <code>_DIRENT_HAVE_D_NAMLEN</code>, <code>_DIRENT_HAVE_D_RECLEN</code>, <code>_DIRENT_HAVE_D_OFF</code>, or <code>_DIRENT_HAVE_D_TYPE</code> are defined.

The value returned in d_off is the same as would be returned by calling telldir(3) at the current position in the directory stream. Be aware that despite its type and name, the d_off field is seldom any kind of directory offset on modern filesystems. Applications should treat this field as an opaque value, making no assumptions about its contents; see also telldir(3).

Other than Linux, the *d_type* field is available mainly only on BSD systems. This field makes it possible to avoid the expense of calling lstat(2) if further actions depend on the type of the file. If the _BSD_SOURCE feature test macro is defined, then glibc defines the following macro constants for the value returned in *d_type*:

DT BLK This is a block device.

DT CHR This is a character device.

DT DIR This is a directory.

DT_FIFO This is a named pipe (FIFO).

DT LNK This is a symbolic link.

DT_REG This is a regular file.

DT SOCK This is a UNIX domain socket.

DT_UNKNOWN The file type is unknown.

If the file type could not be determined, the value $DT_UNKNOWN$ is returned in d_type .

Currently, only some filesystems (among them: Btrfs, ext2, ext3, and ext4) have full support for returning the file type in d_type . All applications must properly handle a return of $DT_UNKNOWN$.

Since POSIX.1 does not specify the size of the d_name field, and other nonstandard fields may precede that field within the dirent

structure, portable applications that use **readdir_r**() should allocate the buffer whose address is passed in *entry* as follows:

(POSIX.1 requires that *d_name* is the last field in a *struct dirent*.)
